

VII. Student's Handbook- Parallel Lines and the Transversal

The following *name game* is perhaps the clearest example of what's really wrong with school-math.

Students worldwide have to memorize these 5 illogical and confusing *names for angle pairs*.

the two lines with arrows are **parallel**

L is a third line called the **transversal**

these four black angles are all **equal**

and

all the white angles are also **equal**

So, we get this very simple pattern:

All the black angles are **equal** to each other and all the white angles are **equal** to each other.

Also, any black and any white angle *together* form *180 degrees, p...*

because they form a **straight line**:

That's all there is to this topic!

But, here's what happens in school-math. *Memorize!*

angle pair <i>names</i>	angle pair <i>examples</i>	are they equal?
corresponding	<i>1</i> and <i>5</i> <i>4</i> and <i>8</i>	equal
corresponding exterior	<i>1</i> and <i>8</i> <i>2</i> and <i>7</i>	not equal even though they are called corresponding
corresponding interior	<i>4</i> and <i>5</i> <i>3</i> and <i>6</i>	not equal even though they are called corresponding
alternate exterior	<i>1</i> and <i>7</i> <i>2</i> and <i>8</i>	equal even though they are called alternate
alternate interior	<i>4</i> and <i>6</i> <i>3</i> and <i>5</i>	equal even though they are called alternate
<i>same side angles:</i>		
vertical should really be called opposite angles	<i>1</i> and <i>3</i> <i>2</i> and <i>4</i>	equal

There are 5 *absurd names* of **angle pairs** in a picture with only 2 *different angles* in it, in the first place. There is nothing more to this topic, no further use for these names later on. These names *never* come up again, ever!

Here's a *trick* to memorize these 5 names and whether the two angles in each pair are equal or not:

corresponding angles are indeed **equal** as the name would seem to imply,

but...

All other **angle pair** with the word **corresponding** in it, the angles are *not equal*

(the opposite of what you would expect)

also...

All **angle pairs** with the word **alternate** in it *are equal*

(again the opposite of what you would expect)

So everything is almost upside-down-world, except for **corresponding angles**.

You “just” need to remember:

corresponding angles means the **angles are equal**,

in *every* other case **corresponding** means *not equal* and **alternate** means **equal**

Ta-Da

The most ridiculous part of this “topic”:

Corresponding angles are **angle pairs** on the *same* side where one is **exterior** and one is **interior**.

What are **angle pairs** on *different* sides where one is **exterior** and one is **interior** called?

corresponding angles

????

corresponding exterior angles

alternate exterior angles

corresponding interior angles

alternate interior angles

That's right, there is *no* name for **angle pairs** (5, 2) (8, 3) (7, 4) (6, 1) !!
